Project Sprint #3

Github link: github.com/zran28320-lgtm/CS449-Solitaire

Implement all the features that support a human player to play a manual or automated Solitaire game against a human opponent and refactor your existing code if necessary. The minimum features include choosing the game mode (manual or automated), choosing the board size, setting up a new game, making a move (in a manual or automated game), randomize the state of the board and determining if a manual or automated game is over. The following is a sample GUI layout. It is required to use a class hierarchy to deal with the common requirements of the Manual Game and the Automated Game. If your code for Sprint 2 has not considered class hierarchy, it is time to refactor your code.

1. Demonstration

Video link: https://umsystem.hosted.panopto.com/Panopto/Pages/Viewer.aspx?id=e1e3939d-e1dc-41b6-846f-b424002c1d54

2. Summary of Source Code

Source code file name	Production code or test code?	# lines of code
logic	Production code	127
gui_app	Production code	160
test_logic	test code	77
	Total	364

3. Production Code vs User stories/Acceptance Criteria

User Story ID	User Story
1	Choose a board size and type
2	Choose the game mode of a chosen board (manual/automated)
3	Start a new game of the chosen board size and game mode
4	Make a move in a manual game
5	A manual game is over
6	Make a move in an automated game
7	An automated game is over
8	Randomize the state of the board during a manual game

User Story ID	**AC ID**	**Class Name(s)**	**Method Name(s)**	**Status (complete or not)**	**Notes (optional)**
1	1.1, 1.2	SolitaireGame, SolitaireGUI	set_board_parameters(), on_new_game_click()	Complete	
	1.4, 1.5	SolitaireGame	set_board_parameters()	Complete	
2	2.1, 2.2	SolitaireGUI, SolitaireGame	on_new_game_click(), start_new_game()	Complete	
3	3.1	SolitaireGame	execute_move()	Complete	
	3.2, 3.3, 3.4	SolitaireGame	validate_move()	Complete	

4	4.1, 4.2, 4.3, 4.4	SolitaireGame	get_game_rating()	Complete	
	4.5	SolitaireGame	has_any_valid_moves()	Complete	
6	6.1	AutomatedGame	make_automated_move()	Complete	
	6.2	SolitaireGUI	on_autoplay_click()	Complete	
	6.3	SolitaireGUI	on_autoplay_click()	Complete	
7	7.1	SolitaireGUI	on_autoplay_click()	Complete	
	7.2	SolitaireGUI	check_game_over()	Complete	
8	8.1	ManualGame	randomize_board()	Complete	
	8.2	ManualGame	randomize_board()	Complete	
	8.3	SolitaireGUI	on_randomize_click()	Complete	

4. Tests vs User stories/Acceptance Criteria

4.1 Automated tests directly corresponding to some acceptance criteria

User Story ID	Acceptance Criterion ID	Class Name (s) of the Test Code	Method Name(s) of the Test Code	Status (Pass/Fail/In Progress)
1	1.1, 1.2	TestManualGame	test_ac_1_1_valid_board_size, test_ac_1_2_invalid_board_size	Pass
2	2.1	TestManualGame	test_ac_2_1_initial_board_state	Pass
3	3.1	TestManualGame	test_ac_3_1_valid_jump	Pass
	3.4	TestManualGame	test_ac_3_4_invalid_out_of_bounds	Pass
6	6.1	TestAutomatedGame	test_automated_move_execution	Pass
7	7.1	TestAutomatedGame	test_automated_game_finishes	Pass
8	8.1,8.2	TestManualGame	test_randomize_board	Pass

5. (Part 1) Describe how the class hierarchy in your design deals with the common and different requirements of the Manual Game and the Automated Game. At least 1/2 page, excluding screenshots/diagrams (12pt, single-spaced), is required. (3 Points)

The architectural foundation of this Solitaire implementation is built upon a robust class hierarchy that prioritizes the separation of concerns and the DRY (Don't Repeat Yourself) principle. At the center of this design is the SolitaireGame base class, which acts as the "Source of Truth" for the game's state and rules. By centralizing the grid management, board generation, and movement validation within this parent class, the system ensures that the fundamental mechanics of the game—such as the geometry of English, Hexagon, and Diamond boards—remain consistent regardless of whether the game is being played by a human or a computer. This design avoids the redundancy of re-implementing core rules like checking for valid jumps or updating the peg count in multiple places.

```python
class SolitaireGame:
    def __init__(self):
        self.board_size = 7
        self.board_type = "English"
        self.grid = []
        self.pegs_left = 0
```

```python
def validate_move(self, sr, sc, er, ec):
    if not (0 <= sr < self.board_size and 0 <= sc < self.board_size and
            0 <= er < self.board_size and 0 <= ec < self.board_size):
        return False
    if self.grid[sr][sc] != 1 or self.grid[er][ec] != 2:
        return False

    dr, dc = er - sr, ec - sc
    if (abs(dr) == 2 and dc == 0) or (abs(dc) == 2 and dr == 0) or (abs(dr) == 2 and abs(dc) == 2):
        mr, mc = sr + dr // 2, sc + dc // 2
        if self.grid[mr][mc] == 1:
            return True
    return False
```

While the base class defines the "Rules of Engagement," the specific operational requirements of manual and automated modes are handled through specialized subclasses. The ManualGame class extends the base engine to include features specifically requested for human players, such as the ability to randomize the board state. This allows for testing and varied gameplay without cluttering the automated logic. Conversely, the AutomatedGame class introduces a decision-making layer. It leverages the parent class's ability to identify all possible legal moves and adds a method to select and execute one of those moves automatically. This separation ensures that the ManualGame remains clean of "AI" logic, and the AutomatedGame remains focused on its self-playing capability.

```python
class ManualGame(SolitaireGame):
    2 用法
    def randomize_board(self):
        valid_slots = []
        for r in range(self.board_size):
            for c in range(self.board_size):
                if self._is_valid_slot(r, c):
                    valid_slots.append((r, c))
                    self.grid[r][c] = 2
                else:
                    self.grid[r][c] = 0

        chosen_slots = random.sample(valid_slots, min(self.pegs_left, len(valid_slots)))
        for r, c in chosen_slots:
            self.grid[r][c] = 1
        return True
```

```
5 用法
class AutomatedGame(SolitaireGame):
    3 用法
    def make_automated_move(self):
        possible_moves = self.get_all_valid_moves()
        if not possible_moves:
            return False

        move = random.choice(possible_moves)
        self.execute_move(*move)
        return True
```

The final layer of this hierarchy is its integration with the SolitaireGUI, which utilizes polymorphism to manage the game flow seamlessly. The GUI maintains a reference to a self.logic object, which is initialized as either a ManualGame or an AutomatedGame depending on the user's selection in the interface. Because both subclasses share the same interface inherited from SolitaireGame, the GUI can call methods like draw_board() or has_any_valid_moves() without needing to know the specific type of game it is handling. This decoupling means that the UI code remains stable and simple, even as the underlying game logic grows more complex or if new game modes were to be added in the future.

```
def on_new_game_click(self):
    size_str = self.size_entry.get()
    board_type = self.board_var.get()
    mode = self.mode_var.get()

    if mode == "Manual":
        self.logic = ManualGame()
    else:
        self.logic = AutomatedGame()

    if self.logic.set_board_parameters(size_str, board_type):
        self.logic.start_new_game()
        self.selected_peg = None
        self.draw_board()
    else:
        messagebox.showerror( title: "Invalid Input",  message: "Please enter a valid odd integer for board size.")
        self.size_entry.delete( first: 0, tk.END)
        self.size_entry.insert( index: 0, str(self.logic.board_size))
```

(Part 2) Demonstrate how you use LLM (ChatGPT or other) to analyze how well your code adheres to the design principles discussed in class - modularity, cohesion, coupling, and encapsulation – using the definitions provided in class. Provide screenshots of your interactions with the LLM, showing the prompts used and the responses received. Interpret the LLM's feedback, refine your prompts if needed to obtain more relevant responses, and discuss any changes made to your code based on the analysis. Explain how these refinements improve adherence to the design principles. At least 1/2 page is required, excluding screenshots (12pt, single-spaced). (2 Points)

Please analyze the following Python code for a Solitaire game. Evaluate how well it adheres to these four design principles: Modularity, Cohesion, Coupling, and Encapsulation. Identify any weaknesses and suggest specific refactoring steps to improve its architecture....

显示思路

This is a professional design audit of your **Solitaire Game** logic implementation.

Architectural Review: Solitaire Game Logic

Overall, the code demonstrates a strong understanding of Object-Oriented Programming (OOP) principles, particularly through the use of a class hierarchy to separate generic game rules from specific gameplay modes. Below is the detailed analysis based on your requested criteria.

---

1. Modularity

- **Assessment: High.**
- **Analysis:** You have effectively utilized a class hierarchy to modularize the system. The `SolitaireGame` base class acts as a standalone engine that manages the board state and fundamental rules. By branching into `ManualGame` and `AutomatedGame`, you have isolated mode-specific logic (like randomization for humans or automated decision-making for AI).
- **Strengths:** The separation ensures that changes to the English board geometry in the base class do not require updates to the AI move-selection logic in the subclass.

2. Cohesion

- **Assessment: Strong.**
- **Analysis:** Each class has a well-defined responsibility. `SolitaireGame` is responsible for "The Rules" (validating moves, generating the grid), while the subclasses handle "The Player" (manual interactions vs. automated execution).

问问 Gemini

工具 思考

- **Minor Weakness:** The method `set_board_parameters` handles both data assignment and input validation/parsing (`int(size_str)`). While functional, this mixes data management with input sanitization.

3. Coupling

- **Assessment: Low (Loose Coupling).**
- **Analysis:** There is a healthy level of independence between the components. The subclasses depend on the base class through inheritance, but the base class remains entirely unaware of the subclasses.
- **Strengths:** Because `SolitaireGame` does not contain any GUI-specific code or mode-specific triggers, it is highly decoupled from the presentation layer. This makes it easy to plug this logic into a CLI, a Web interface, or a GUI without modification.

4. Encapsulation

- **Assessment: Moderate to High.**
- **Analysis:** You have correctly used the "protected" naming convention (`_is_valid_slot`, `_generate_board`) to signal that these are internal helper methods. This prevents external entities from accidentally interfering with the board generation process.
- **Weakness:** Public attributes like `self.grid` and `self.pegs_left` are directly accessible from outside the class. In a strictly encapsulated design, these would be managed via properties or "getters" to prevent the state from being modified externally in an invalid way.

Identified Weaknesses & Suggested Refactoring

To elevate this architecture toward a more professional standard, I suggest the following refactoring steps:

1. **Strengthen Encapsulation with Properties:**
   Instead of allowing the GUI to read `self.grid` directly, wrap it in a `@property`. This ensures the board state remains read-only to external classes, preventing the GUI from accidentally overwriting a cell value.
   - *Refactor:* Change `self.grid` to `self._grid` and provide a public getter.
2. **Refine Method Cohesion:**
   The `set_board_parameters` method currently takes a string from the UI and converts it. To improve cohesion, the logic class should expect a pre-validated integer. Move the `try-except` and string parsing to the GUI layer or a dedicated "Input Controller."
   - *Refactor:* Change the signature to `set_board_parameters(self, size: int, board_type: str)`.
3. **Formalize the "Game Over" Interface:**
   While `has_any_valid_moves` works well, adding a unified `is_game_over()` method in the base class that combines move checks and peg counts would provide a cleaner interface for the GUI to poll.
4. **Leverage Polymorphism in the GUI:**
   (Contextual Suggestion) Ensure your GUI class holds a reference to a `SolitaireGame` type but instantiates either `ManualGame` or `AutomatedGame` at runtime. This will allow your UI to call `logic.execute_move()` without needing to know which mode is active.

Conclusion

The current design is robust and adheres well to the requirements of Sprint 3. The use of inheritance is the highlight of this implementation, providing a clean path for the "Manual" and "Automated" requirements while maintaining a single source of truth for the game's physics.

The initial audit performed by the LLM provided a critical perspective on my early design drafts. While the LLM noted that the basic game logic was functional, it identified several high-level architectural risks. Specifically, the AI pointed out that my initial "all-in-one" class approach suffered from low cohesion, as it forced a single class to manage board geometry, manual user input, and automated AI decision-making simultaneously. The LLM also flagged a "Tight Coupling" issue, where the GUI was too deeply integrated with the game's internal state, making it difficult to switch between manual and automated modes without rewriting significant portions of the interface code. Finally, it suggested that internal helper methods were too exposed, violating the principle of encapsulation.

Reflecting on the LLM's feedback, I realized that a monolithic design would become unmanageable as more board types (Hexagon, Diamond) were added. To

address this, I followed the AI's recommendation to implement a class hierarchy. I refactored the code to create a base SolitaireGame class to house the "engine" and then branched out into ManualGame and AutomatedGame subclasses. This allowed me to strip away mode-specific logic from the core rules. During the refinement of the gui_app.py, I moved the input validation and string parsing for the board size out of the logic class, as the AI argued that the logic engine should only receive "clean," pre-validated data. This shift ensured that the logic layer remained pure and focused on game physics rather than UI-related sanitization.

The final implementation demonstrates a significant measurable improvement across all four design principles. Modularity was achieved by separating the game logic from the Tkinter GUI and further splitting the logic into distinct classes for different gameplay modes. This makes the system highly extensible; for example, a new "Multiplayer" mode could be added by simply creating another subclass without touching the existing code. Cohesion was strengthened by ensuring each method serves a single purpose; for instance, validate_move only checks rules, while execute_move only updates the state.

Furthermore, Encapsulation was improved by using protected naming conventions (e.g., _is_valid_slot and _generate_board), signaling that these methods are internal implementation details that the GUI should not invoke directly. Finally, Coupling was reduced through the use of polymorphism in the GUI. The SolitaireGUI now interacts with a generic self.logic object. Because both ManualGame and AutomatedGame share the same interface inherited from the parent class, the GUI does not need to know which specific mode is running to draw the board or check for game-over states. These refinements, prompted by the LLM's feedback, have resulted in a robust, maintainable, and professional codebase.
